Quick definitions  
(*Pointer*)

**noun:** a strong slender smooth-haired dog of Spanish origin having a white coat with brown or black patches; scents out and points game

**noun:** an indicator as on a dial

**noun:** (computer science) indicator consisting of a movable spot of light (an icon) on a visual display; moving the cursor allows the user to point to commands or screen positions

**noun:** a mark to indicate a direction or relation

**name:** A surname (rare: 1 in 33333 families; popularity rank in the U.S.: #3808)

PRIMARY-EXAMINER: Choules; Jack

ATTY-AGENT-FIRM: Brinks Hofer Gilson & Lione

ABSTRACT:

A system and method to provide buyers with information that supports the selection of qualified vendors and service providers at the precise time they are prepared to make a purchase. To accomplish its function, the system includes three core elements: (1) a data retrieval system that makes it easy for ready and willing buyers to find and contact qualified businesses; (2) a proprietary electronic database with enhanced information regarding local businesses; (3) an electronic distribution network that employs live, enhanced directory assistance (EDA) operators via telephone as well as the World Wide Web, and simplifies the connections between motivated buyers and qualified sellers. Buyers are able to search the database of businesses to find the most qualified providers of goods/service that match their unique criteria. Sellers can use the service to better promote their offerings to a market that has moved beyond window shopping and that is ready to buy.

## Architectural roots

Pointers are a very thin abstraction on top of the addressing capabilities provided by most modern architectures. In the simplest scheme, an *address*, or a numeric index, is assigned to each unit of memory in the system, where the unit is typically either a [byte](#) or a [word](#), effectively transforming all of memory into a very large [array](#). Then, if we have an address, the system provides an operation to retrieve the value stored in the memory unit at that address. Pointers are [datatypes](#) which hold addresses. See [reference \(computer science\)](#).

In the usual case, a pointer is large enough to hold more different addresses than there are units of memory in the system. This introduces the possibility that a program may attempt to access an address which corresponds to no unit of memory, called a [segmentation fault](#). On the other hand, some systems

have more units of memory than there are addresses. In this case, a more complex scheme such as segmentation or paging is employed to use different parts of the memory at different times.

In order to provide a consistent interface, some architectures provide memory-mapped I/O, which allows some addresses to refer to units of memory while others refer to device registers of other devices in the computer. There are analogous concepts such as file offsets, array indices, and remote object references that serve some of the same purposes as addresses for other types of objects.

## Uses

Pointers, which are directly supported without restrictions in C, C++, and most assembly languages, are primarily used for constructing references, which in turn are fundamental in constructing nearly all data structures, as well as in passing data between different parts of a program.

When dealing with arrays, the critical lookup operation typically involves a stage called *address calculation* which involves constructing a pointer to the desired data element in the array. In other data structures, such as linked lists, pointers are used as references to explicitly tie one piece of the structure to another.

## Typed pointers and casting

In many languages, pointers have the additional restriction that the object they point to has a specific type. For example, a pointer may be declared to point to an integer; the language will then attempt to prevent the programmer from pointing it to objects which are not integers, such as floating-point numbers, eliminating some errors.

However, few languages strictly enforce pointer types, because programmers often run into situations where they *want* to treat an object of one type as though it were of another type. For these cases, it is possible to typecast, or cast, the pointer. Some casts are always safe, while other casts are dangerous, possibly resulting in incorrect behavior later on. Although it's impossible in general to determine at compile-time which of these casts are safe, some languages store run-time type information which can be used to confirm that these dangerous casts are valid at runtime.

## Making pointers safer

Because pointers are so close to the hardware, they enable a variety of programming errors. However, the power they provide is so great that it's difficult to do anything useful without them. To help deal with their problems, many languages have created objects that have some of the useful features of pointers, while avoiding some of their pitfalls.

One major problem with pointers is that, as long as they can be directly manipulated as a number, they can be made to point to unused addresses or to data which is being used for other purposes. Many languages, including most functional programming languages and recent imperative languages like Java, replace pointers with references, which can only be used to refer to objects and not manipulated as numbers, preventing this type of error. Array indexing is handled as a special case.

Before any address has been assigned to it, a pointer is called a wild pointer. Any attempt to use such uninitialized pointers can cause unexpected behaviour, either because the initial address is not a valid address, or because using it may damage the runtime system and other unrelated parts of the program.

In systems with explicit memory allocation, it's possible to create a "dangling" pointer, by deallocating the memory region it points into. This type of pointer is dangerous and subtle, because a deallocated memory region looks the same as it did before, but can be reused at any time by unrelated code. Languages with garbage collection prevent this type of error.

Some languages, like C++, support smart pointers, which use a simple form of reference counting to help track allocation of dynamic memory in addition to acting as a reference. In the absence of reference cycles, where an object refers to itself indirectly through a sequence of smart pointers, these eliminate the possibility of use of dangling pointers and memory leaks.

## The *null* pointer

The null pointer is a pointer with a reserved value indicating that it refers to no object. Null pointers are used routinely, particularly in C, to represent exceptional conditions such as the lack of a successor to the last element of a linked list, while maintaining a consistent structure for the list nodes. This use of null pointers can be compared to the use of null values in relational databases. Because it refers to nothing, an attempt to dereference a null pointer causes a run-time error that usually terminates the programming immediately. In safe languages a possibly null pointer can be replaced with a tagged union which enforces explicit handling of the exceptional case.

## Pointer support in various programming languages

### C

In C, pointers are variables that store addresses and can be null. Each pointer has a type it points to, but one can freely cast between pointer types. A special pointer type called the **void pointer** points to an object of unknown type. The address can be directly manipulated by casting a pointer to and from an integer. Pointer arithmetic is unrestricted; adding or subtracting from a pointer moves it by a multiple of the size of the datatype it points to.

### C++

C++ is a derivative of C which fully supports C pointers and C typecasting. It also supports a new group of typecasting operators to help catch some unintended dangerous casts at compile-time. The C++ standard library also provides autoptr, a sort of smart pointer which can be used in some situations as a safe alternative to primitive C pointers.

### Ada

Ada is a strongly typed language where all pointers are typed and only safe type conversions are permitted. All pointers are by default initialized to *null*, and any attempt to access data through a *null* pointer causes an exception to be raised. Pointers in Ada are called *access types*. Ada-83 did not permit arithmetic on *access types* (although many compiler vendors provided for it as a non-standard feature), but Ada-95 supports "safe" arithmetic on *access types* via the package `System.Storage_Elements`.

### Pascal

Pascal implements pointers in a straightforward, limited, and relatively safe way. It is a strongly typed

language (with few exceptions) and a pointer to any declared variable may used. Memory which contains no variable may not be referenced in this way. Parameters may be passed using pointers (as VAR parameters) but are automatically handled by the runtime system.

+++assistance is needed here, eg in contrast with freedom of C et al+++

## Modula 2

Pointers are implemented very much as in Pascal, as are VAR parameters in procedure calls. Modula 2 is even more strongly typed than Pascal, with fewer ways to escape the type system. Some of the variants of Modula 2 (such as Modula-3) include garbage collection. +++assistance is needed here+++

## Oberon

Much as with Modula-2, pointers are available. There are still fewer ways to evade the type system and so Oberon and its variants are still safer with respect to pointers than Modula-2 or its variants. As with Modula-3, garbage collection is a part of the language specification. +++assistance is needed here+++

ABSTRACT:

In one embodiment, systems and methods are used to maintain client relationships by tracking and managing customers and agents involved in booking a cruise. Furthermore, various activities which take place between an agent and active customers are monitored, whereby the type and quantity of activities performed by the agent is evaluated to assign a period of time of ownership of the customer. During the period of time while the customer is owned, other agents are prevented from acquiring the customer and subsequent booking commission. A series of rules which determine the duration of ownership of the customer are maintained and applied to enable the ownership to be changed as needed.

ABSTRACT:

A method and apparatus for authenticating, archiving information and updating ownership of unique items by associating a unique identifying code with the item. Ownership history of the item is locked with a PIN or Personal Identification Number of the owner and cannot be changed until the owner releases the PIN. A new owner then associates his PIN with the item.

ABSTRACTED-PUB-NO: US 6189003B

BASIC-ABSTRACT:

NOVELTY - At least one search template is derived dynamically, based on a search request received from the user. The database is search electrically, using the

derived search template, to identify at least one business based on the search request.

DETAILED DESCRIPTION - Initially, at least one search criteria defined through research about companies in at least one category of business, is identified. Then, the business directory data comprising a business name, address and telephone number is obtained for at least one business listing. At least one category attribute representative of at least one business listing, is developed to facilitate categorical classification of business listing. Then, search template is dynamically derived, for searching directory database to identify at least one business according to the search result. The business transaction with at least one business identified in response to the search result, is then completed. The request for proposal to the identified business is submitted. An INDEPENDENT CLAIM is also included for search templates derivation system for searching directory data.

USE - For deriving search templates to identify business directory data in electronic yellow pages, Internet yellow pages and operator assisted yellow pages services.

ADVANTAGE - Since electronic distribution network is coupled to the database, connections between motivated buyers and qualified sellers is facilitated reliably. Provides more detailed search tool capable of refining and targeting the search process to find a qualified vendor of products/services in an electronic directory, narrowing down a list of potential candidates having the highest relevancy matching the user's specific search criteria. Enables the user to broadcast the specific, unique purchase related request to targeted candidates via electronic platform.

DESCRIPTION OF DRAWING(S) - The figure shows the flowchart explaining the search template deriving method.

ABSTRACTED-PUB-NO: WO 200025190A

ABSTRACTED-PUB-NO: US20020174022A

BASIC-ABSTRACT:

NOVELTY - Seller databases (32a-32n) are identified by pointers associated with selected product class. A search interface communicates a search query for product data, only to seller databases associated with sellers (30a-30n), having attribute values matching set seller attribute criteria, in response to selection of the product class and specification of seller attribute criteria.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

- (1) Method of pre-qualifying sellers; and
- (2) Program for providing seller pre-qualification.

USE - For providing seller pre-qualification during matching phase of e-commerce transaction.

ADVANTAGE - Allows buyers to pre-qualify sellers based on seller attribute values in addition to product attribute values. Simplifies and increases the speed of

matching phase of e-commerce transaction in which buyer searches for suitable product and/or suitable seller.

DESCRIPTION OF DRAWING(S) - The figure shows an e-commerce system.

Sellers 30a-30n

Seller databases 32a-32n

ABSTRACT:

A method and apparatus of automatically matching sellers of property with potential buyers through a communications network (preferably the Internet) in which a host system communicates with the sellers and the potential buyers over telephone or dedicated data transmission lines. The host system obtains and stores a first set of records each corresponding to a property to be sold. The first set of records can then be search by a remote data terminal associated with a potential buyer. The results of this search are then provided to the potential buyer, who indicates specific property listings that the potential buyer may be interested in purchasing. The potential buyer provides identifying information which is then provided to the sellers of the indicated property. Provisions are made to ensure that the sellers who list property support the system. Further, the system permits automatic evaluation of potential buyers to screen buyers whose information does not match minimum criteria provided by the seller.
